The revolution in hearing aids occurred about a decade ago when the transition from analog to digital technology took place. Where analog technology amplified all sounds equally, digital technology made hearing aids much smarter—giving them the ability to amplify meaningful sounds (such as speech), while making background noise less important.

But increased precision, comfort and clarity were just the beginning of the benefits this digital revolution enabled:

**Help with hearing in noise**
One of the biggest challenges people with hearing loss have is hearing clearly in noisy places like restaurants or at social gatherings. The best of today’s hearing aids remedy that with directional technology that zeroes in on companions’ voices while suppressing the cacophony around you. They also:

- Virtually eliminate feedback (buzzing and whistling)
- Adjust automatically to your listening environment
- Work effortlessly with phones

**Wireless connectivity**
The latest advancement is wireless hearing aids. With wireless, sound from your TV, computer, MP3 player or phone is streamed right into your ears at the volume you choose and control. This direct connection results in more immersive, enhanced sound, as you’re now able to listen at the volume you want without having to turn the volume up loud in the room.

**Invisible devices**
Best of all, digital technology has enabled all these new features and benefits to fit in advanced hearing solutions that are getting smaller and smaller all the time—with some so tiny they rest completely in your ear canal, virtually undetectable when worn.
